

## What this study could and could not have seen

Schoenfeld approximation at alpha = 0.05

This is the honest reading of every null result. The negative control (amber) had 80% power only for HR  $\geq 1.99$ , so its null result rules out a LARGE surveillance effect, not a modest one of, say, 1.5. The male estimate needed HR  $\geq 4.65$  to be detectable, so its apparent size reflects low power as much as a genuinely larger effect.
