

Cumulative incidence of seizure, with death as a competing event

Aalen-Johansen. 3-year risk: 2.25% (IIH) vs 0.83% (control); difference 1.43 pp, NNH 70

1 – Kaplan-Meier is NOT shown: it would overstate absolute risk by treating the deceased as still at risk. Note the death panel: mortality is markedly LOWER in the IIH arm, which may be real or may reflect differential death ascertainment (controls carry no date fields at all).
