

The association is fragile to unrecorded seizures in controls

Tipping-point analysis: the null is reached at roughly 1% hidden events among censored controls

This is the study's most serious quantitative vulnerability, and it is the direct consequence of a very low control event count (83 events among 9,742 controls). The null negative-control result (carpal tunnel HR 0.89) is the main evidence AGAINST such gross differential under-ascertainment.
