

The BMI interaction does not survive a continuous analysis

Continuous BMI x IIH interaction p = 0.558 (the dichotomised subgroup test gave p = 0.028)

Splitting BMI at 35 produced an apparently significant interaction. Modelled continuously the gradient is flat and the interaction disappears. This is what dichotomising a continuous modifier does: it can manufacture effect modification. The continuous result is the trustworthy one, and it says the effect is uniform across BMI.
