

What this study could and could not have seen

Schoenfeld approximation at alpha = 0.05

This is the honest reading of every null result. The negative control (amber) had 80% power only for HR >= 1.99, so its null result rules out a LARGE surveillance effect, not a modest one of, say, 1.5. The male estimate needed HR >= 4.65 to be detectable, so its apparent size reflects low power as much as a genuinely larger effect.
