

The excess risk is sustained, not concentrated at diagnosis

Smoothed scaled Schoenfeld residuals from the 3-year model, day 180 onward

A detection artefact arising from the diagnostic work-up would spike early and decay. It does not. The band is an approximate pointwise interval from the residual scatter, not a formal confidence band; the formal test of non-proportionality is in S16 ($p = 0.98$ at 3 years).
