

Every specification points the same way

Hazard ratio for seizure or epilepsy, IIH versus matched comparators. Log scale.

Eight specifications: four outcome definitions crossed with two encounter definitions. All are significant, and all fall between 1.9 and 2.9. The epilepsy-specific-code row is the one that matters most: under the arm-asymmetric ascertainment of the submitted analysis it read 0.50 and pointed the other way, and with both arms scored identically it agrees with the primary. Clinical visits only is the proposed primary because it is the more conservative of the two.
