

Timing of incident events

Years from index. The 180-day washout means no event can fall before 0.49 years. Note the differing y scales.

66 events in the IIH arm, 63 among comparators. Median latency 450 days (IQR 268 to 666) and 382 days (254 to 692). Events concentrate early in BOTH arms: 61% of IIH events and 67% of comparator events fall within the first year after the washout, tailing off thereafter (IIH 18 then 8 events in years two and three; comparators 13 then 8). Early concentration in a single arm would suggest prevalent disease being recorded late, or surveillance triggered by the index event. Seen equally in both arms it cannot distinguish those explanations from a genuine early hazard -- it neither supports nor undermines the primary result. What the panel does show is that the two distributions have the same shape: the arms differ in how MANY events occur, not in when they occur.
