

Of the patients who had a seizure, how many went on to epilepsy

One square = one patient. Dark = recurrent or established epilepsy; light = a single seizure event.

Outcome-positive patients only (IIH 102, control 64). Epilepsy = two or more coded seizures at least 30 days apart, OR an epilepsy-specific G40/345 code or established-disease descriptor, OR antiseizure medication continued 180 days or more. Ascertained from index to last attended encounter, not to the seizure, since recurrence occurs after the first event. The control block is drawn in grey because its 98% is NOT comparable to the IIH figure: 63 of its 64 patients carry an epilepsy-specific code, consistent with the control outcome having required stronger evidence before it was called. Topiramate, gabapentin and clobazam are excluded from the medication channel, being IIH and pain therapies.
