

When do the seizures happen?

Median 2.46 y in IIH vs 1.68 y in controls (Wilcoxon $p = 0.0515$), among those with an event

Only 55% of IIH events fall within three years, against 80% of control events: the exposed hazard persists well beyond the primary window. This argues AGAINST the events being an artefact of the diagnostic work-up, which would cluster them immediately after index. Conditional on having an event, so not an effect estimate.
