

Of the patients who had a seizure, how many had recurrent disease

Recurrent = two or more coded seizures 30+ days apart, an epilepsy-specific code, or indefinite antiseizure therapy.

Outcome-positive patients only: 66 with IIH, 63 comparators. Both arms classified by the same rule on the same clock. The difference between the arms is in how OFTEN seizures occur, not in how likely they are to recur once they do: the confidence intervals on these proportions overlap (62%, 49 to 74, against 51%, 38 to 64).
