

Which evidence identified epilepsy

Among outcome-positive patients. Channels overlap; a patient meeting any one is classified as epilepsy.

Denominators are the outcome-positive patients in each arm (IIH 102, control 64). The medication channel is not comparable between arms: only 17 of 102 IIH patients have any antiseizure medication record against 48 of 64 controls, and the commonest agent recorded in cases is fosphenytoin, an intravenous acute-seizure drug. The case medication file records inpatient administrations; the control file records outpatient prescriptions.
